# MACROECONOMICS

N. GREGORY MANKIW

## National Income: Where It Comes From and Where It Goes

# IN THIS CHAPTER, YOU WILL LEARN:

---

- What determines the economy's total output/income
- How the prices of the factors of production are determined
- How total income is distributed
- What determines the demand for goods and services
- How equilibrium in the goods market is achieved

# Outline of model

A closed economy, market-clearing model

- Supply side
  - factor markets (supply, demand, price)
  - determination of output/income
- Demand side
  - determinants of **C**, **I**, and **G**
- Equilibrium
  - goods market
  - loanable funds market

# Factors of production

**$K$**  = capital:  
tools, machines, and structures used in  
production

**$L$**  = labor:  
the physical and mental efforts of  
workers

# The production function: $Y = F(K, L)$

- Shows how much output ( $Y$ ) the economy can produce from  $K$  units of capital and  $L$  units of labor
- Reflects the economy's level of technology
- Exhibits constant returns to scale

# Returns to scale: a review

Initially  $Y_1 = F(K_1, L_1)$

Scale all inputs by the same factor  $z$ :

$$K_2 = zK_1 \text{ and } L_2 = zL_1$$

(e.g., if  $z = 1.2$ , then all inputs are increased by 20%)

What happens to output,  $Y_2 = F(K_2, L_2)$ ?

- If **constant returns to scale**,  $Y_2 = zY_1$
- If **increasing returns to scale**,  $Y_2 > zY_1$
- If **decreasing returns to scale**,  $Y_2 < zY_1$

# Assumptions

1. Technology is fixed.
2. The economy's supplies of capital and labor are fixed at:

$$K = \bar{K} \quad \text{and} \quad L = \bar{L}$$

# Determining GDP

Output is determined by the fixed factor supplies and the fixed state of technology:

$$\bar{Y} = F(\bar{K}, \bar{L})$$

# The distribution of national income

- determined by **factor prices**,  
the prices per unit firms pay for the factors of production
  - wage = price of  $L$
  - **rental rate** = price of  $K$

# Notation

**$W$**  = nominal wage

**$R$**  = nominal rental rate

**$P$**  = price of output

**$W/P$**  = real wage  
(measured in units of output)

**$R/P$**  = real rental rate

# How factor prices are determined

- Factor prices are determined by supply and demand in factor markets.
- Recall: Supply of each factor is fixed.
- What about demand?

# Demand for labor

- Assume markets are competitive:  
each firm takes  **$W$** ,  **$R$** , and  **$P$**  as given.
- Basic idea:  
A firm hires each unit of labor  
if the cost does not exceed the benefit.
  - cost = real wage
  - benefit = marginal product of labor

# Marginal product of labor (*MPL*)

- Definition:

The extra output the firm can produce using an additional unit of labor (holding other inputs fixed):

$$MPL = F(K, L+1) - F(K, L)$$

# ***MPL* and the production function**

# Diminishing marginal returns

- As one input is increased (holding other inputs constant), its marginal product falls.
- Intuition:  
If  $L$  increases while holding  $K$  fixed  
machines per worker falls,  
worker productivity falls.

# ***MPL* and the demand for labor**

# The equilibrium real wage

# Determining the rental rate

- We have just seen that  $MPL = W/P$ .
- The same logic shows that  $MPK = R/P$ :
  - Diminishing returns to capital:  
 $MPK$  falls as  $K$  rises
  - The  $MPK$  curve is the firm's demand curve for renting capital.
  - Firms maximize profits by choosing  $K$  such that  $MPK = R/P$ .

# The equilibrium real rental rate

# The neoclassical theory of distribution

- States that each factor input is paid its marginal product
- A good starting point for thinking about income distribution

# How income is distributed to $L$ and $K$

$$\text{Total labor income} = \frac{W}{P} \bar{L} = \mathbf{MPL} \times \bar{L}$$

$$\text{Total capital income} = \frac{R}{P} \bar{K} = \mathbf{MPK} \times \bar{K}$$

If production function has constant returns to scale, then

$$\bar{Y} = \underbrace{\mathbf{MPL} \times \bar{L}}_{\text{labor income}} + \underbrace{\mathbf{MPK} \times \bar{K}}_{\text{capital income}}$$

national income

# How income is distributed to $L$ and $K$

**What About Profit? Define economic profit as:**

$$\text{Economic Profit} = Y - \left(\frac{W}{P} \times L\right) - \left(\frac{R}{P} \times K\right)$$

$$\text{Economic Profit} = Y - (MPL \times L) - (MPK \times K)$$

***If production function is CRS, then:***

$$Y = (MPL \times L) + (MPK \times K)$$

***so that Economic Profit = 0***

# How income is distributed to $L$ and $K$

**Example of Euler's Theorem. To see this, use definition of CRS:**

$$zY = F(zL, zK)$$

***Differentiate with respect to  $z$ :***

$$Ydz = F_1(zL, zK)Ldz + F_2(zL, zK)Kdz$$

***and set  $z = 1$  to obtain:***

$$Y = F_1(L, K)L + F_2(L, K)K$$

# How income is distributed to $L$ and $K$

$$\begin{aligned} Y &= F_1(L, K)L + F_2(L, K)K \\ &= (MPL \times L) + (MPK \times K) \end{aligned}$$

**where**

$$\begin{aligned} F_1(L, K) &= MPL \\ F_2(L, K) &= MPK \end{aligned}$$

# The ratio of labor income to total income in the U.S., 1960-2010

# The Cobb-Douglas production function

- The Cobb-Douglas production function has constant factor shares:

$\alpha$  = capital's share of total income:

$$\text{capital income} = MPK \times K = \alpha Y$$

$$\text{labor income} = MPL \times L = (1 - \alpha) Y$$

- The Cobb-Douglas production function is:

$$Y = AK^\alpha L^{1-\alpha}$$

where  $A$  represents the level of technology.

# The Cobb-Douglas production function

- Each factor's marginal product is proportional to its average product:

$$MPK = \alpha AK^{\alpha-1} L^{1-\alpha} = \frac{\alpha Y}{K}$$

$$MPL = (1-\alpha) AK^{\alpha} L^{-\alpha} = \frac{(1-\alpha)Y}{L}$$

# Labor productivity and wages

- Theory: wages depend on labor productivity
- U.S. data:

<i>period</i>	<i>productivity growth</i>	<i>real wage growth</i>
1960-2013	2.1%	1.8%
1960-1973	2.9%	2.7%
1973-1995	1.5%	1.2%
1995-2013	2.3%	2.0%

# The growing gap between rich & poor

# Explanations for rising inequality

1. Rise in capital's share of income, since capital income is more concentrated than labor income
2. From *The Race Between Education and Technology* by Goldin & Katz
  - Technological progress has increased the demand for skilled relative to unskilled workers.
  - Due to a slowdown in expansion of education, the supply of skilled workers has not kept up.
  - Result: Rising gap between wages of skilled and unskilled workers.

# Demand for goods and services

Components of aggregate demand:

***C*** = consumer demand for g&s

***I*** = demand for investment goods

***G*** = government demand for g&s

(closed economy: no ***NX***)

# Consumption, $C$

- **Disposable income** is total income minus total taxes:  $Y - T$ .
- Consumption function:  $C = C(Y - T)$
- Definition: **Marginal propensity to consume (MPC)** is the change in  $C$  when disposable income increases by one dollar.

# The consumption function

# Investment, $I$

- The investment function is  $I = I(r)$   
where  $r$  denotes the **real interest rate**,  
the nominal interest rate corrected for inflation.
- The real interest rate is:
  - the cost of borrowing
  - the opportunity cost of using one's own funds to finance investment spending

So,  $I$  depends negatively on  $r$

# The investment function

# Government spending, $G$

- $G$  = govt spending on goods and services
- $G$  excludes transfer payments  
(e.g., Social Security benefits,  
unemployment insurance benefits)
- Assume government spending and total taxes  
are exogenous:

$$G = \bar{G} \quad \text{and} \quad T = \bar{T}$$

# The market for goods & services

- Aggregate demand:  $\mathbf{C}(\bar{\mathbf{Y}} - \bar{\mathbf{T}}) + \mathbf{I}(\mathbf{r}) + \bar{\mathbf{G}}$

- Aggregate supply:  $\bar{\mathbf{Y}} = \mathbf{F}(\bar{\mathbf{K}}, \bar{\mathbf{L}})$

- Equilibrium:  $\bar{\mathbf{Y}} = \mathbf{C}(\bar{\mathbf{Y}} - \bar{\mathbf{T}}) + \mathbf{I}(\mathbf{r}) + \bar{\mathbf{G}}$

The real interest rate adjusts  
to equate demand with supply.

# The loanable funds market

- A simple supply–demand model of the financial system.
- One asset: “loanable funds”
  - demand for funds: investment
  - supply of funds: saving
  - “price” of funds: real interest rate

# Demand for funds: investment

The demand for loanable funds . . .

- comes from investment:  
Firms borrow to finance spending on plant & equipment, new office buildings, etc.  
Consumers borrow to buy new houses.
- depends negatively on  $r$ ,  
the “price” of loanable funds  
(cost of borrowing).

# Loanable funds demand curve

The investment curve is also the demand curve for loanable funds.

# Supply of funds: saving

- The supply of loanable funds comes from saving:
  - Households use their saving to make bank deposits, purchase bonds and other assets. These funds become available to firms to borrow and finance investment spending.
  - The government may also contribute to saving if it does not spend all the tax revenue it receives.

# Types of saving

$$\text{Private saving} = (Y - T) - C$$

$$\text{Public saving} = T - G$$

$$\text{National saving, } S$$

$$= \text{private saving} + \text{public saving}$$

$$= (Y - T) - C + T - G$$

$$= Y - C - G$$

## ***Notation:* $\Delta$ = change in a variable**

- For any variable  $X$ ,  $\Delta X$  = “change in  $X$ ”

$\Delta$  is the Greek (uppercase) letter *Delta*

Examples:

- If  $\Delta L = 1$  and  $\Delta K = 0$ , then  $\Delta Y = MPL$ .

More generally, if  $\Delta K = 0$ , then  $MPL = \frac{\Delta Y}{\Delta L}$ .

- $\Delta(Y - T) = \Delta Y - \Delta T$ , so

$$\begin{aligned}\Delta C &= MPC \times (\Delta Y - \Delta T) \\ &= MPC \Delta Y - MPC \Delta T\end{aligned}$$

# Budget surpluses and deficits

- If  $T > G$ , **budget surplus** =  $(T - G)$   
= public saving.
- If  $T < G$ , **budget deficit** =  $(G - T)$   
and public saving is negative.
- If  $T = G$ , **balanced budget**, public saving = 0.
- The U.S. government finances its deficit by issuing Treasury bonds—*i.e.*, borrowing.

# U.S. federal government surplus/deficit, 1940-2016

# U.S. federal government debt, 1940-2016

# Loanable funds supply curve

National saving does not depend on  $r$ , so the supply curve is vertical.

# Loanable funds market equilibrium

# The special role of $r$

$r$  adjusts to equilibrate the goods market *and* the loanable funds market simultaneously:

If L.F. market in equilibrium, then

$$Y - C - G = I$$

Add ( $C + G$ ) to both sides to get

$$Y = C + I + G \text{ (goods market eq'm)}$$

Thus,

Eq'm in L.F.  
market

Eq'm in goods  
market

# Mastering the loanable funds model

Things that shift the saving curve:

- public saving
  - fiscal policy: changes in  $G$  or  $T$
- private saving
  - preferences
  - tax laws that affect saving
    - 401(k)
    - IRA
    - replace income tax with consumption tax

# CASE STUDY:

## The Reagan Deficits

- Reagan policies during early 1980s:
  - increases in defense spending:  $\Delta \mathbf{G} > 0$
  - big tax cuts:  $\Delta \mathbf{T} < 0$
- Both policies reduce national saving:

$$\bar{\mathbf{S}} = \bar{\mathbf{Y}} - \mathbf{C}(\bar{\mathbf{Y}} - \bar{\mathbf{T}}) - \bar{\mathbf{G}}$$

$$\uparrow \bar{\mathbf{G}} \Rightarrow \downarrow \bar{\mathbf{S}}$$

$$\downarrow \bar{\mathbf{T}} \Rightarrow \uparrow \mathbf{C} \Rightarrow \downarrow \bar{\mathbf{S}}$$

# CASE STUDY: The Reagan Deficits

1. The increase in the deficit reduces saving...

2. ...which causes the real interest rate to rise...

3. ...which reduces the level of investment.

## ***Are the data consistent with these results?***

	1970s	1980s
<b><i>T – G</i></b>	–2.2	–3.9
<b><i>S</i></b>	19.6	17.4
<b><i>r</i></b>	1.1	6.3
<b><i>I</i></b>	19.9	19.4

*T–G, S, and I are expressed as a percent of GDP  
All figures are averages over the decade shown.*

# Mastering the loanable funds model

## *(continued)*

Things that shift the investment curve:

- some technological innovations
  - to take advantage of some innovations, firms must buy new investment goods
- tax laws that affect investment
  - e.g., investment tax credit

# An increase in investment demand

# Saving and the interest rate

- Why might saving depend on  $r$  ?
- How would the results of an increase in investment demand be different?
  - Would  $r$  rise as much?
  - Would the equilibrium value of  $I$  change?

# An increase in investment demand when saving depends on $r$

An increase in investment demand raises  $r$ , which induces an increase in the quantity of saving, which allows  $I$  to increase.

# CHAPTER SUMMARY

---

- Total output is determined by:
  - the economy's quantities of capital and labor
  - the level of technology
- Competitive firms hire each factor until its marginal product equals its price.
- If the production function has constant returns to scale, then labor income plus capital income equals total income (output).

# CHAPTER SUMMARY

---

- A closed economy's output is used for consumption, investment, and government spending.
- The real interest rate adjusts to equate the demand for and supply of:
  - goods and services.
  - loanable funds.

# CHAPTER SUMMARY

---

- A decrease in national saving causes the interest rate to rise and investment to fall.
- An increase in investment demand causes the interest rate to rise but does not affect the equilibrium level of investment if the supply of loanable funds is fixed.
