

6

# MACROECONOMICS

N. GREGORY MANKIW

## The Open Economy

# IN THIS CHAPTER, YOU WILL LEARN:

---

- Accounting identities for the open economy
- The small open economy model
  - what makes it “small”
  - how the trade balance and exchange rate are determined
  - how policies affect trade balance & exchange rate

# Imports and exports of selected countries, 2013

## **In an open economy,**

- spending need not equal output
- saving need not equal investment

# Preliminaries

$$\mathbf{C} = \mathbf{C}^d + \mathbf{C}^f$$

$$\mathbf{I} = \mathbf{I}^d + \mathbf{I}^f$$

$$\mathbf{G} = \mathbf{G}^d + \mathbf{G}^f$$

superscripts:

$d$  = spending on  
domestic goods

$f$  = spending on  
foreign goods

$\mathbf{EX}$  = exports =  
foreign spending on domestic goods

$\mathbf{IM}$  = imports =  $\mathbf{C}^f + \mathbf{I}^f + \mathbf{G}^f$   
= spending on foreign goods

$\mathbf{NX}$  = net exports (*a.k.a.* the “trade balance”)  
=  $\mathbf{EX} - \mathbf{IM}$

**GDP = Expenditure on  
domestically produced g&s**

$$Y = C^d + I^d + G^d + EX$$

$$= (C - C^f) + (I - I^f) + (G - G^f) + EX$$

$$= C + I + G + EX - (C^f + I^f + G^f)$$

$$= C + I + G + EX - IM$$

$$= C + I + G + NX$$

# The national income identity in an open economy

$$Y = C + I + G + NX$$

or,  $NX = Y - (C + I + G)$

The diagram illustrates the components of the national income identity. A green box labeled 'net exports' has an arrow pointing to the  $NX$  term in the equation. A purple box labeled 'output' has an arrow pointing to the  $Y$  term. A blue box labeled 'domestic spending' has a bracket underneath it, which points to the  $(C + I + G)$  term, indicating that these three components together represent domestic spending.

# Trade surpluses and deficits

$$NX = EX - IM = Y - (C + I + G)$$

- **Trade surplus:**

output > spending and exports > imports

Size of the trade surplus =  **$NX$**

- **Trade deficit:**

spending > output and imports > exports

Size of the trade deficit =  **$-NX$**

# International capital flows

- **Net capital outflow**

- =  $S - I$

- = net outflow of “loanable funds”

- = net purchases of foreign assets

- the country's purchases of foreign assets  
minus foreign purchases of domestic assets

- When  $S > I$ , country is a *net lender*

- When  $S < I$ , country is a *net borrower*

# The link between trade & cap. flows

$$NX = Y - (C + I + G)$$

*implies*

$$\begin{aligned} NX &= (Y - C - G) - I \\ &= S - I \end{aligned}$$

*trade balance = net capital outflow*

Thus,  
a country with a trade deficit ( $NX < 0$ )  
is a net borrower ( $S < I$ ).

# Saving, investment, and the trade balance 1960–2014

# U.S.: the world's largest debtor nation

- Every year since the 1980s: huge trade deficits and net capital inflows, *i.e.*, net borrowing from abroad
- As of 12/31/2014:
  - U.S. residents owned \$24.7 trillion worth of foreign assets
  - Foreigners owned \$31.6 trillion worth of U.S. assets
  - U.S. net indebtedness to rest of the world: \$6.9 trillion—higher than any other country, hence U.S. is the “world's largest debtor nation”

# Saving and investment in a small open economy

- An open-economy version of the loanable funds model from Chapter 3.
- Includes many of the same elements:

- production function

$$Y = \bar{Y} = F(\bar{K}, \bar{L})$$

- consumption function

$$C = C(Y - T)$$

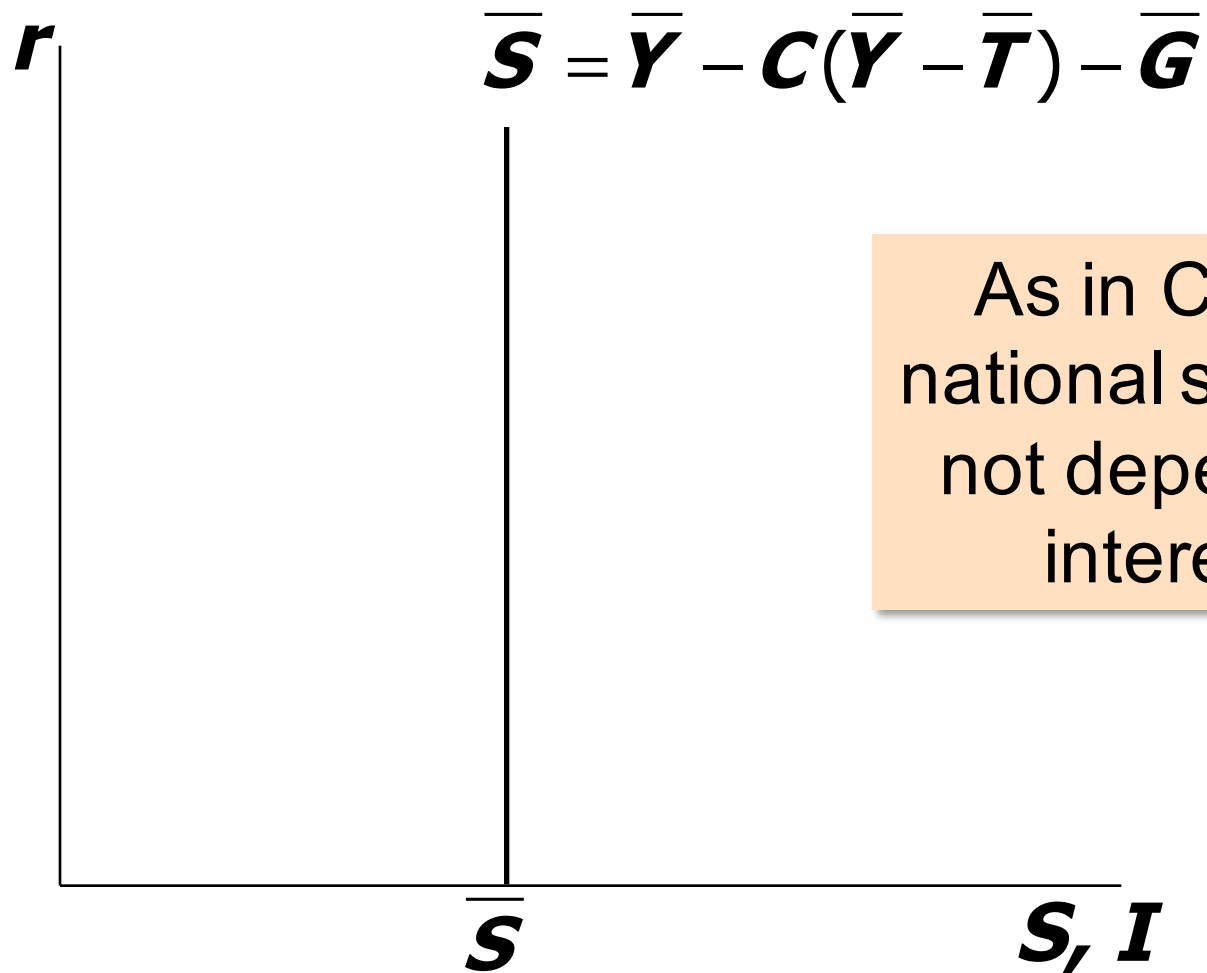

- investment function

$$I = I(r)$$

- exogenous policy variables

$$G = \bar{G}, \quad T = \bar{T}$$

# National saving: The supply of loanable funds

As in Chapter 3,  
national saving does  
not depend on the  
interest rate

# Assumptions about capital flows

- a. Domestic & foreign bonds are perfect substitutes (same risk, maturity, etc.)
- b. **Perfect capital mobility**:  
no restrictions on international trade in assets
- c. Economy is **small**:  
cannot affect the world interest rate, denoted  $r^*$

a & b imply  $r = r^*$   
c implies  $r^*$  is exogenous

# Investment:

## The demand for loanable funds

## ***If the economy were closed . . .***

. . . the interest rate would adjust to equate investment and saving.

## ***But in a small open economy...***

the exogenous world interest rate determines investment...

...and the difference between saving and investment determines net capital outflow and net exports

# The nominal exchange rate

**e** = nominal exchange rate,  
the relative price of  
domestic currency  
in terms of foreign currency  
(*e.g.*, yen per dollar)

## A few exchange rates, as of 1/13/2015

<i>country</i>	<i>exchange rate</i>
Euro area	0.85 euro/\$
Indonesia	12,576 rupiahs/\$
Japan	118.0 yen/\$
Mexico	14.6 pesos/\$
Russia	65.85 rubles/\$
South Africa	11.50 rand/\$
U.K.	0.66 pounds/\$

# The real exchange rate

*the lowercase  
Greek letter  
epsilon*

$\epsilon$  = real exchange rate,  
the relative price of  
domestic goods  
in terms of foreign goods  
(e.g. Japanese Big Macs per  
U.S. Big Mac)

# Understanding the units of $\varepsilon$

$$\begin{aligned}\varepsilon &= \frac{\mathbf{e} \times \mathbf{P}}{\mathbf{P}^*} \\&= \frac{(\text{Yen per \$}) \times (\$ \text{ per unit U.S. goods})}{\text{Yen per unit Japanese goods}} \\&= \frac{\text{Yen per unit U.S. goods}}{\text{Yen per unit Japanese goods}} \\&= \frac{\text{Units of Japanese goods}}{\text{per unit of U.S. goods}}\end{aligned}$$

# $\epsilon$ in the real world & our model

- In the real world:  
We can think of  $\epsilon$  as the relative price of a basket of domestic goods in terms of a basket of foreign goods.
- In our macro model:  
There's just one good, "output."  
So  $\epsilon$  is the relative price of one country's output in terms of the other country's output.

# How $NX$ depends on $\varepsilon$

If  $\varepsilon$  rises:

- U.S. goods become more expensive relative to foreign goods
- exports fall, imports rise
- net exports fall

# U.S. net exports and the real exchange rate, 1973-2014

# The net exports function

- The **net exports function** reflects this inverse relationship between  $NX$  and  $\epsilon$ :

$$NX = NX(\epsilon)$$

# The $NX$ curve for the U.S.

# The $NX$ curve for the U.S.

# How $\epsilon$ is determined

- The accounting identity says  $NX = S - I$
- We saw earlier how  $S - I$  is determined:
  - $S$  depends on domestic factors (output, fiscal policy variables, etc.)
  - $I$  is determined by the world interest rate  $r^*$
- So,  $\epsilon$  must adjust to ensure

$$NX(\epsilon) = \bar{S} - I(r^*)$$

# How $\epsilon$ is determined

Neither  $S$  nor  $I$  depends on  $\epsilon$ , so the net capital outflow curve is vertical.

$\epsilon$  adjusts to equate  $NX$  with net capital outflow,  $S - I$ .

# Interpretation: supply and demand in the foreign exchange market

## ***Demand:***

Foreigners need dollars to buy U.S. net exports.

## ***Supply:***

Net capital outflow ( $S - I$ ) is the supply of dollars to be invested abroad.

# Four experiments:

1. Fiscal policy at home
2. Fiscal policy abroad
3. An increase in investment demand (exercise)
4. Trade policy to restrict imports

# 1. Fiscal policy at home

A fiscal expansion reduces national saving, net capital outflow, and the supply of dollars in the foreign exchange market...

...causing the real exchange rate to rise and ***NX*** to fall.

# NX and the federal budget deficit (% of GDP), 1965–2014

## 2. Fiscal policy abroad

An increase in  $r^*$  reduces investment, increasing net capital outflow and the supply of dollars in the foreign exchange market...

...causing the real exchange rate to fall and  $NX$  to rise.

## NOW YOU TRY

### 3. Increase in investment demand

Determine the impact of an increase in investment demand on net exports, net capital outflow, and the real exchange rate.

# ANSWERS

## 3. Increase in investment demand

An increase in investment reduces net capital outflow and the supply of dollars in the foreign exchange market...

...causing the real exchange rate to rise and  $NX$  to fall.

## 4. Trade policy to restrict imports

At any given  $\epsilon$ , an import quota reduces  $IM$ , increases  $NX$ , increases demand for dollars.

Trade policy doesn't affect  $S$  or  $I$ , so capital flows and the supply of dollars remain fixed.

## 4. Trade policy to restrict imports

*Results:*

$$\Delta \epsilon > 0$$

(demand  
increase)

$$\Delta NX = 0$$

(supply fixed)

$$\Delta IM < 0$$

(policy)

$$\Delta EX < 0$$

(rise in  $\epsilon$ )

# The determinants of the nominal exchange rate

- Start with the expression for the real exchange rate:

$$\boldsymbol{\varepsilon} = \frac{\boldsymbol{e} \times \boldsymbol{P}}{\boldsymbol{P}^*}$$

- Solve for the nominal exchange rate:

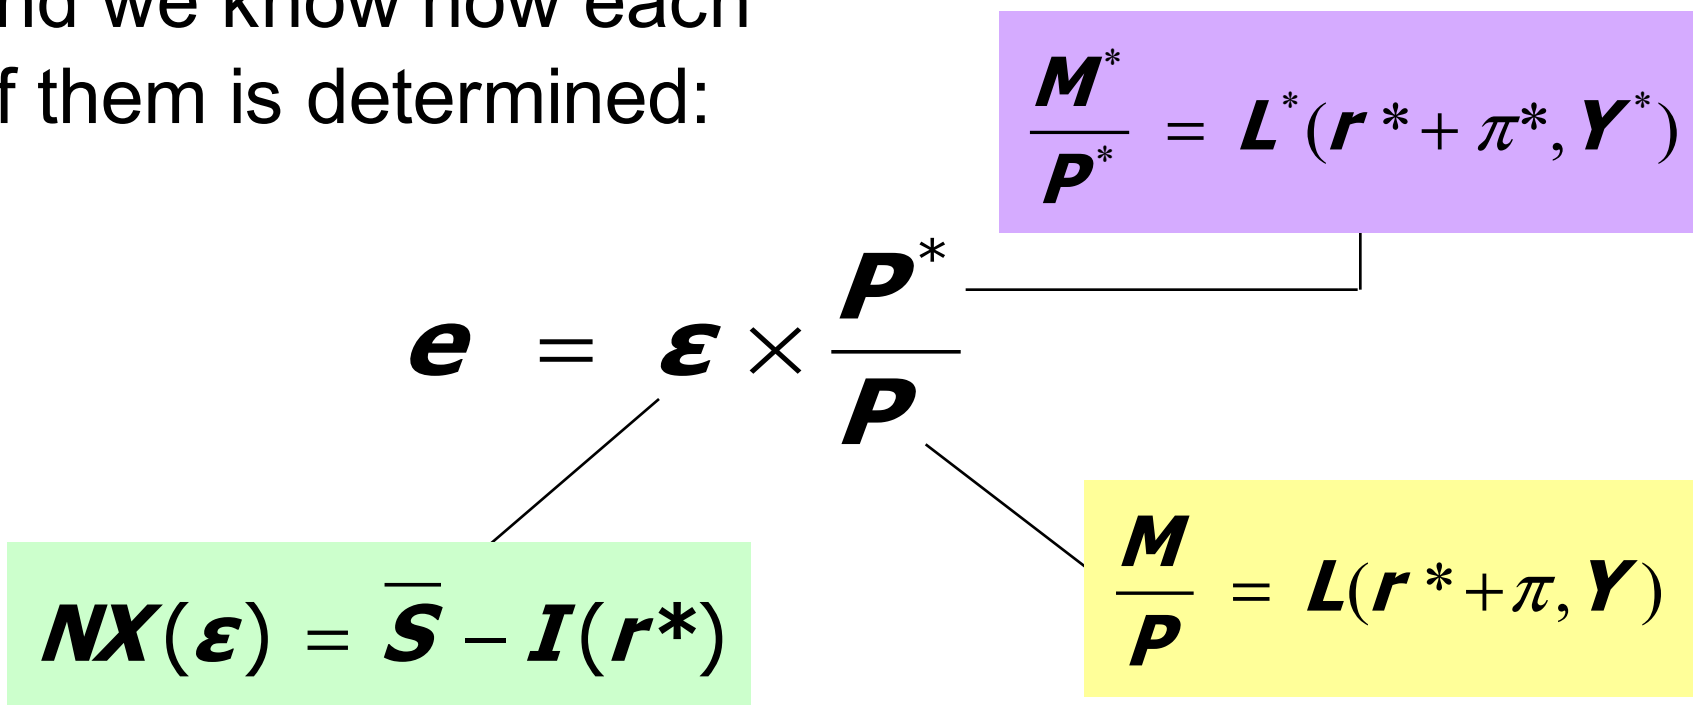

$$\boldsymbol{e} = \boldsymbol{\varepsilon} \times \frac{\boldsymbol{P}^*}{\boldsymbol{P}}$$

# The determinants of the nominal exchange rate

- So  $e$  depends on the real exchange rate and the price levels at home and abroad . . .

and we know how each of them is determined:

$$e = \varepsilon \times \frac{P^*}{P}$$

The diagram illustrates the determinants of the nominal exchange rate  $e$ . The central equation is  $e = \varepsilon \times \frac{P^*}{P}$ . Three lines point from the variables in this equation to their respective determining equations:

- $\varepsilon$  is determined by  $NX(\varepsilon) = \bar{S} - I(r^*)$  (shown in a green box).
- $P^*$  is determined by  $\frac{M^*}{P^*} = L^*(r^* + \pi^*, Y^*)$  (shown in a purple box).
- $P$  is determined by  $\frac{M}{P} = L(r^* + \pi, Y)$  (shown in a yellow box).

# The determinants of the nominal exchange rate

$$\mathbf{e} = \boldsymbol{\varepsilon} \times \frac{\mathbf{P}^*}{\mathbf{P}}$$

- Rewrite this equation in growth rates  
(see “*arithmetic tricks for working with percentage changes*,” Chapter 2 ):

$$\frac{\Delta \mathbf{e}}{\mathbf{e}} = \frac{\Delta \boldsymbol{\varepsilon}}{\boldsymbol{\varepsilon}} + \frac{\Delta \mathbf{P}^*}{\mathbf{P}^*} - \frac{\Delta \mathbf{P}}{\mathbf{P}} = \frac{\Delta \boldsymbol{\varepsilon}}{\boldsymbol{\varepsilon}} + \pi^* - \pi$$

- For a given value of  $\boldsymbol{\varepsilon}$ ,  
the growth rate of  $\mathbf{e}$  equals the difference  
between foreign and domestic inflation rates.

# Inflation differentials and nominal exchange rates for a cross section of countries

# Purchasing Power Parity (PPP)

Two definitions:

- A doctrine that states that goods must sell at the same (currency-adjusted) price in all countries.
- The nominal exchange rate adjusts to equalize the cost of a basket of goods across countries.

Reasoning:

- arbitrage, the law of one price

# Purchasing Power Parity (PPP)

- PPP:

$$e \times P = P^*$$

The diagram shows the equation  $e \times P = P^*$ . A bracket under  $e \times P$  has a line pointing to a pink box. A line from  $P^*$  points to a blue box. A line from  $P$  points to a yellow box.

Cost of a basket of foreign goods, in foreign currency.

Cost of a basket of domestic goods, in foreign currency.

Cost of a basket of domestic goods, in domestic currency.

- Solve for  $e$ :  $e = P^*/P$
- PPP implies that the nominal exchange rate between two countries equals the ratio of the countries' price levels.

# Purchasing Power Parity (PPP)

- If  $e = P^*/P$ ,  
then  $\epsilon = e \times \frac{P}{P^*} = \frac{P^*}{P} \times \frac{P}{P^*} = 1$   
and the  $NX$  curve is horizontal:

Under PPP,  
changes in  
( $S - I$ ) have no  
impact on  $\epsilon$  or  $e$ .

# Does PPP hold in the real world?

No, for two reasons:

1. International arbitrage not possible
  - nontraded goods
  - transportation costs
2. Different countries' goods not perfect substitutes

Yet, PPP is a useful theory:

- It's simple & intuitive.
- In the real world, nominal exchange rates tend toward their PPP values over the long run.

## CASE STUDY: The Reagan Deficits Revisited

	1970s	1980s	actual change	closed economy	small open economy
<b><math>G - T</math></b>	2.2	3.9	↑	↑	↑
<b><math>S</math></b>	19.6	17.4	↓	↓	↓
<b><math>r</math></b>	1.1	6.3	↑	↑	no change
<b><math>I</math></b>	19.9	19.4	↓	↓	no change
<b><math>NX</math></b>	-0.3	-2.0	↓	no change	↓
<b><math>\varepsilon</math></b>	115.1	129.4	↑	no change	↑

*Data: Decade averages; all except  $r$  and  $\varepsilon$  are expressed as a percent of GDP;  $\varepsilon$  is a trade-weighted index.*

# The U.S. as a large open economy

- So far, we've learned long-run models for two extreme cases:
  - closed economy (Chapter 3)
  - small open economy (Chapter 5)
- A large open economy—like the U.S.—falls between these two extremes.
- The results from large open economy analysis are a mixture of the results for the closed & small open economy cases.
- For example . . .

# A fiscal expansion in three models

A fiscal expansion causes national saving to fall.  
The effects of this depend on openness & size.

	<i>closed economy</i>	<i>large open economy</i>	<i>small open economy</i>
<i>r</i>	rises	rises, but not as much as in closed economy	no change
<i>I</i>	falls	falls, but not as much as in closed economy	no change
<i>NX</i>	no change	falls, but not as much as in small open economy	falls

# CHAPTER SUMMARY

---

- Net exports—the difference between:
  - exports and imports
  - a country's output ( $Y$ ) and its spending ( $C + I + G$ )
- Net capital outflow equals:
  - purchases of foreign assets minus foreign purchases of the country's assets
  - the difference between saving and investment

# CHAPTER SUMMARY

---

- National income accounts identities
  - $Y = C + I + G + NX$
  - trade balance  $NX = S - I$  net capital outflow
- Impact of policies on  $NX$ 
  - $NX$  increases if policy causes  $S$  to rise or  $I$  to fall
  - $NX$  does not change if policy affects neither  $S$  nor  $I$ . Example: trade policy

# CHAPTER SUMMARY

---

- Exchange rates
  - nominal: the price of a country's currency in terms of another country's currency
  - real: the price of a country's goods in terms of another country's goods
  - The real exchange rate equals the nominal rate times the ratio of prices of the two countries.

# CHAPTER SUMMARY

---

- How the real exchange rate is determined
  - **$NX$**  depends negatively on the real exchange rate, other things equal
  - The real exchange rate adjusts to equate  **$NX$**  with net capital outflow

# CHAPTER SUMMARY

---

- How the nominal exchange rate is determined:
  - $e$  equals the real exchange rate times the country's price level relative to the foreign price level.
  - For a given value of the real exchange rate, the percentage change in the nominal exchange rate equals the difference between the foreign & domestic inflation rates.
